**Diphyllobothrium latum**

**Scientific name:** Diphyllobothrium latum  
**English names:** “Bothriocephalus”(1), “fish tapeworm”  
**Helminths**  
**Phylum:** Plathelminths (flatworms)  
**Parasite**

---

**Characteristics and sources of Diphyllobothrium latum**

**Main microbiological characteristics**

*Diphyllobothrium* is a flat tapeworm (class Cestoda, Order Pseudophylidia, family Diphyllobothriidae) around ten meters long that can live for several years. It is responsible for a gastrointestinal parasitic infection called diphyllobothriasis.

The life cycle of the parasite (Figure 1) involves a definitive host (2): humans (and other fish-eating mammals) and at least two intermediate hosts (3): a planktonic crustacean and one or more freshwater fish. In favourable environmental conditions, the eggs (4 x 65 µm), after being released in freshwater with the faeces of the definitive host, complete their maturation in 8-12 days and then hatch and release a ciliated embryo, the coracidium. This is ingested by a microscopic crustacean of the genera *Cyclops* or *Eudiaptomus* and turns into larvae (called procercoids) within the body cavity. When a carnivorous fish ingests this planktonic crustacean, the larva turns into a second type of larva (called plerocercoids), a few millimeters long. This becomes encysted in the musculature or viscera of the fish. Humans and other fish-eating mammals then become contaminated after ingesting the raw or undercooked flesh of these freshwater fish. Once in the intestine of the definitive host, the plerocercoid larva grows by several centimeters a day and the first eggs are released with faeces, approximately one month after infestation. Several species of this parasite are pathogenic for humans, but only *D. latum* can be contracted from freshwater fish found in mainland France. However, cases of infestation by *D. nihonkaiense* (Pacific species) have been observed among consumers of salmon (*Onchorhynchus* sp.) imported from the Pacific (Canada).

**Sources of the hazard**

The source of the hazard consists of carnivorous freshwater or anadromous (i.e. living in both fresh and salt water) fish.

The reservoir consists of the parasite’s definitive hosts (humans, cats, dogs, foxes, etc.) and its intermediate hosts (carnivorous fish).

---

(1) The name Bothriocephalus should no longer be used because it corresponds to a different genus of intestinal parasite of many species of fish that differs from the genus Diphyllobothrium.  
(2) Definitive host: host that harbours the adult parasite.  
(3) Intermediate host: host that harbours the larval form of the parasite.
Prevalence

Diphyllobothriasis is a cosmopolitan parasitosis, consistently found in Western Europe. It is decreasing in the Baltic or Scandinavian countries that were its historical foci. However, it seems to be emerging in the French- and Italian-speaking areas of the perialpine lakes where commercial fishing is common. Since 1987, over 200 cases have been reported or published around the lakes Geneva, Murten, Biel, Maggiore, Como, Iseo and Garda. Lake Geneva seems particularly affected, with 48 cases of contamination being identified on its Swiss and French watersheds in 2001 and 2002. Between 2002 and 2007, 44 cases were identified in the medical analysis laboratories of Haute-Savoie.

Role of foods

Main foods to consider

Foods involved are the raw flesh (marinated fillets, carpaccio, etc.) or raw eggs of freshwater fish: perch (Perca fluviatilis), pike (Esox lucius), Arctic char (Salvelinus alpinus), burbot (Lota lota), etc. Four to ten per cent of perch fillets consumed on the banks of Lake Geneva carry the parasite. Coregonid fish (fera) and probably European salmonids of the genus Salmo are resistant to D. latum. Canadian salmonids of the genus Onchorhynchus may host larvae of D. nihonkaiense.

Inactivation treatments in industrial environments

Foodborne human disease

Nature of the disease (Table 1)

Susceptible population group(s) (5)

There is no evidence to date to suggest that there is a population at higher risk of infection or complications.

Dose-effect (6) and dose-response (7) relationships

A single plerocercoid larva can cause infestation.

Epidemiology

Monitoring system

There is no system for monitoring diphyllobothriasis in France or Europe (except in Poland and the Baltic states).

</table>

(4) This vitamin B12 deficiency anaemia has been described in cases of prolonged multiple infestation in undernourished populations because the worm absorbs this vitamin.
(5) Susceptible population group: people with a higher than average probability of developing symptoms of the disease, or severe forms of the disease, after exposure to a foodborne hazard [definition used in ANSES data sheets].
(6) Relationship between the dose (the quantity of microbial cells ingested during a meal) and the effect on an individual.
(7) For a given effect, the relationship between the dose and the response, i.e., the probability of this effect appearing in the population.
Monitoring in food

There are no regulations on detection of the parasite applicable to foodstuffs identified as being at risk. There is no standardised method for detecting, counting and typing. The plerocercoid larvae can be observed by direct examination of fillets cut into thin strips. Due to the presence of larvae of other similar parasites, molecular identification is useful for confirming species diagnosis.

Recommendations to operators
- With regard to collective hygiene, treatment of wastewater in modern sewage plants is able to interrupt the transmission cycle.
- The usual food hygiene measures (washing of food, hands, etc.) have no effect on the larvae, nor does storage in the refrigerator.
- The European Regulation (8) requires freezing of the flesh of fish intended to be eaten raw in restaurants.

Domestic hygiene

Storage of fish in the refrigerator does not affect the survival of the parasite. Freezing ensures inactivation.

Recommendations to consumers
- Cooking (65°C) or freezing (for 7 days in a domestic freezer) fish are the only measures to avoid contamination.
